electricity using thermoelectric devices finds numerous especially around room temperature. However, the relatively high material processing cost limits their real applications. Silver selenide  $(Ag_2Se)$  is one of the very few n-type thermoelectric (TE) materials for room-temperature applications. Herein, we report a room temperature, fast, and aqueous-phase synthesis approach to produce Ag<sub>2</sub>Se, which can be extended to other metal chalcogenides. These materials reach TE figures of merit (*zT*) of up to 0.76 at 380 K. To improve these values, bismuth sulfide  $(Bi<sub>2</sub>S<sub>3</sub>)$  particles also prepared

in an aqueous solution are incorporated into the Ag<sub>2</sub>Se matrix. In this way, a series of Ag<sub>2</sub>Se/Bi<sub>2</sub>S<sub>3</sub> composites with Bi<sub>2</sub>S<sub>3</sub> wt % of 0.5, 1.0, and 1.5 are prepared by solution blending and hot-press sintering. The presence of  $Bi<sub>2</sub>S<sub>3</sub>$  significantly improves the Seebeck coefficient and power factor while at the same time decreasing the thermal conductivity with no apparent drop in electrical conductivity. Thus, a maximum  $zT$  value of 0.96 is achieved in the composites with 1.0 wt %  $Bi<sub>2</sub>S<sub>3</sub>$  at 370 K. Furthermore, a high average *zT* value (*zT*ave) of 0.93 in the 300−390 K range is demonstrated.

KEYWORDS: *thermoelectricity, silver selenide, aqueous synthesis, bismuth sulfide, composite*

## ■ **INTRODUCTION**

Thermoelectric (TE) devices allow for direct, solid state, and reversible conversion between heat and electricity.<sup>1−[4](#page-6-0)</sup> TE devices can harvest heat from the ambient environment, potentially increasing the efficiency of a plethora of processes. They also allow precise control of the temperature and effective cooling of hot spots. However, their real-world applications are limited to several niche markets due to their relatively low cost-effectiveness. The high cost of TE devices is related to the use of scarce elements such as Te, the need for high-temperature or vacuum-based processes for the synthesis of TE materials, and the quasimanual manufacturing of TE modules. Alternative printing technologies are being developed worldwide, but the use of organic solvents for the synthesis of the materials and/or the ink formulation is still a major drawback to the environmentally friendly and low-cost processing of TE devices. On top of the high cost, the energy conversion efficiency of TE devices is relatively low. The energy conversion efficiency of a TE material is determined by a dimensionless figure of merit

$$
zT = S^2 \sigma T / k \tag{1}
$$

where *S*,  $\sigma$ ,  $\kappa$ , and  $T$  are the Seebeck coefficient  $(\mu V K^{-1})$ , electrical conductivity  $(\text{S m}^{-1})$ , thermal conductivity  $(\text{W m}^{-1})$ K<sup>−</sup><sup>1</sup> ), and absolute temperature (K), respectively. *κ* includes the electronic thermal conductivity  $(\kappa_e)$  and lattice thermal conductivity  $(\kappa_L)$ :

$$
\kappa = \kappa_{\rm e} + \kappa_{\rm L} \tag{2}
$$

Besides,  $S^2\sigma$  is defined as the power factor (PF). A good TE material is thus characterized by high S and *σ*, and low *κ* values.

Silver selenide  $(Ag_2Se)$  is one of the very few TE materials suitable for use at ambient temperature, where it is characterized by relatively low thermal conductivity and high electrical conductivity. $^{5}$  $^{5}$  $^{5}$  Ag<sub>2</sub>Se is an n-type semiconductor with a narrow band gap ( $E_{\rm g}$  = 0.07 eV at 0 K). It exists in two stable phases, the low-temperature orthorhombic *β*-phase and the high-temperature cubic *α*-phase, with a transition temperature of around 407 K. $6-8$  $6-8$  $6-8$  Numerous approaches exist for the synthesis of Ag2Se. Among them, the commonly reported solid-state preparation strategy is based on reacting the two elements, Ag and Se, at high temperatures<sup>[6,9](#page-6-0)–[15](#page-6-0)</sup> or using high-energy ball milling.<sup>[8](#page-6-0),[16](#page-6-0)</sup> As an example, Chen et al. developed a porous Ag2Se with hierarchical structures via a wet mechanical alloying process. Using this approach, a low lattice thermal conductivity of ~0.35 W m<sup>-1</sup> K<sup>-1</sup> and a zT of ~0.7 were obtained at 300 K.<sup>[8](#page-6-0)</sup> Besides, Ag<sub>2</sub>Se is also produced by

Figure 1. (a) Schematic illustration of the synthesis of binary metal chalcogenides (MX; M = Ag, Cu, Pb, Bi; X = S, Se). (b−d) SEM images of Ag<sub>2</sub>Se produced from AgNO<sub>3</sub>:Se molar ratios of (b) 2:1, (c) 1.9:1, and (d) 1.8:1. (e) XRD patterns of Ag<sub>2</sub>Se.

vacuum-based technologies such as magnetron sputtering.<sup>17</sup> Various chemical synthetic methods have also been reported for the production of silver chalcogenides and particularly Ag<sub>2</sub>Se particles, including colloidal,<sup>[18](#page-6-0)-[21](#page-6-0)</sup> hydrothermal,<sup>[22,23](#page-7-0)</sup> and microwave-assisted $24$  methods. In some cases, aqueous solutions have been used.<sup>[5](#page-6-0),[25](#page-7-0),[26](#page-7-0)</sup> As an example, Xiao et al. synthesized Ag2Se nanocrystals via a colloidal method, reaching a maximum *zT* value of 0.23 at the phase transition temperature of around 408 K.<sup>[19](#page-6-0)</sup> Wang et al. reported a general aqueous synthesis of nano/microscale binary silver chalcogenides (Ag<sub>2</sub>X, X = S, Se, Te) based on the reaction of Na<sub>2</sub>S/  $NaHSe/NaHTe$  and  $AgNO<sub>3</sub>$  aqueous solution at the water boiling temperature. The molar ratios of  $\text{Ag}^{+}/\text{X}^{2-}$  were adjusted from 2:1 to 2:1.1 and the maximum *zT* value of the resulting Ag<sub>2</sub>Se pellet was 0.84 at 380 K.<sup>[25](#page-7-0)</sup>

The TE properties of pristine Ag<sub>2</sub>Se can be improved through extrinsic and intrinsic doping. Li et al. reported a hydrothermal solution route using ethylene glycol and glycerol as solvents to prepare Ag<sub>2</sub>Se at 180  $^{\circ}$ C, reaching a maximum  $zT$  of 0.7 at 317 K for Ag<sub>2</sub>Se, and up to 0.9 at 300 K when adding 0.1 wt % Sn doping at Ag sites.<sup>[27](#page-7-0)</sup> Variations in the stoichiometric ratio of silver to selenium were also investigated to control the concentration of free carriers, showing an obvious effect on the TE performance.<sup>[11](#page-6-0),[16,17](#page-6-0)</sup> In this direction, Jood et al. introduced an anion excess (≤1% of Se or S) into Ag<sub>2</sub>Se obtaining a notable improvement in carrier mobility and zT values up to ∼1.0 in the temperature range of 300−375  $K^{13,14}$  $K^{13,14}$  $K^{13,14}$  $K^{13,14}$  $K^{13,14}$  Another important approach to improving Ag<sub>2</sub>Se performance is to combine it with small amounts of other materials into nanocomposites.<sup>[28](#page-7-0)−[31](#page-7-0)</sup> As an example, Ballikaya et al. added  $Cu<sub>2</sub>Se$  nanoinclusions in Ag<sub>2</sub>Se to improve the TE performance and thermal stability.<sup>[32](#page-7-0)</sup> Lim et al. obtained a high  $zT$  of 0.89 at 343 K through the simple blending of Ag<sub>2</sub>Se with Te nanorods.<sup>18</sup> Besides, carbon nanotubes were also used as an effective nanofiller for enhancing the TE performance of  $Ag_2Se.<sup>5,23</sup>$  $Ag_2Se.<sup>5,23</sup>$  $Ag_2Se.<sup>5,23</sup>$  $Ag_2Se.<sup>5,23</sup>$ 

Bismuth sulfide  $(Bi_2S_3)$  is an n-type semiconductor composed of relatively abundant, nontoxic, and low-cost elements.<sup>33</sup> Bi<sub>2</sub>S<sub>3</sub> has poor zT values at ambient temperature, because of moderate electrical conductivity. However, it is characterized by high Seebeck coefficients (ca. −400 *μ*V/K) and low thermal conductivities.  $Bi_2S_3$  has been used as a doping phase to promote the TE properties of some TE materials, including  $Cu_{1.8}S^{34}$  $Cu_{1.8}S^{34}$  $Cu_{1.8}S^{34}$  and  $Bi_2Te_{2.7}Se_{0.3}^{35}$  $Bi_2Te_{2.7}Se_{0.3}^{35}$  $Bi_2Te_{2.7}Se_{0.3}^{35}$ 

Herein, we detail a facile, rapid, room temperature, and aqueous-based general approach to producing highly crystalline Ag<sub>2</sub>Se. Besides, a series of Ag<sub>2</sub>Se-x wt %  $Bi<sub>2</sub>S<sub>3</sub>$  (x = 0, 0.5,

1.0 and 1.5) nanocomposites is produced by solution-blending and hot pressing. Interestingly, the incorporation of  $Bi_2S_3$ results in a significant increase in the Seebeck coefficient. Furthermore, the optimized composition shows low thermal conductivity and a record-high *zT* of 0.96 at 370 K.

## ■ **EXPERIMENTAL SECTION**

**Materials.** Silver(I) nitrate  $(AgNO<sub>3</sub>, 99.9+%)$ , copper(II) nitrate trihydrate  $(Cu(NO<sub>3</sub>)<sub>2</sub>·3H<sub>2</sub>O, 99%)$ , lead(II) nitrate  $(Pb(NO<sub>3</sub>)<sub>2</sub>, 99+$ %), and hydrazine hydrate  $(N_2H_4·H_2O, 64%)$  were supplied by Fisher Scientific. Selenium powder (Se, 200 mesh,  $\geq$  99.5% trace metals basis), bismuth nitrate pentahydrate  $(Bi(NO<sub>3</sub>)<sub>3</sub>·5H<sub>2</sub>O, \ge 99.99%),$ thioacetamide (TAA,  $\geq$  99.0%), and nitric acid (HNO<sub>3</sub>, 68%) were purchased from Sigma-Aldrich. All chemicals were used without further purification using standard solution synthesis procedures.  $36,37$ 

**Synthesis of Silver Selenide.** In a typical synthetic method,  $0.8494$  g of AgNO<sub>3</sub> was dissolved into 10 mL of deionized water (DIW). In parallel, a Se precursor solution was prepared by adding 0.2078 g of Se powder to 5 mL of  $N_2H_4 \cdot H_2O$ . The AgNO<sub>3</sub> aqueous solution was then injected at ambient temperature into the Se solution, where a black precipitate was immediately formed. The product was collected by centrifugation and washed using DIW and ethanol three times. The final product was dried and stored in an Arfilled glovebox.

**Synthesis of Metal Chalcogenide (MX).** For the production of other binary metal chalcogenides (MX,  $M = Cu$ , Pb, Bi;  $X = S$ , Se) a similar synthesis strategy was adopted. The detailed parameters are shown in [Table](https://pubs.acs.org/doi/suppl/10.1021/acsaelm.3c00055/suppl_file/el3c00055_si_001.pdf) S1. It is worth mentioning that SnS and SnSe can also be prepared by the same approach in an alkaline water environment (e.g., sodium hydroxide aqueous solution), but they require a longer reaction time (ca. 1 h) at ambient temperature.

**Synthesis of Bismuth Sulfide.** Bi<sub>2</sub>S<sub>3</sub> was synthesized in an aqueous solution following an alternative procedure inspired by previous publications.<sup>[38](#page-7-0),[39](#page-7-0)</sup> Briefly, TAA  $(0.510 \text{ g})$  was dissolved in 160 mL of DIW with rapid stirring. At the same time,  $Bi(NO<sub>3</sub>)<sub>3</sub>·5H<sub>2</sub>O$  $(1.584 \text{ g})$  was added to 20 mL of 0.4 M HNO<sub>3</sub> aqueous solution, and then it was added drop by drop to the TAA solution. The mixture was reacted for 15 h at room temperature with continuous strong stirring. The coarse product solution was washed with DIW and ethanol five times. Finally, it was dried and stored in an Ar-filled glovebox.

**Nanopowder Blend and Consolidation.** Ag<sub>2</sub>Se/Bi<sub>2</sub>S<sub>3</sub> composite powders were produced by blending the proper ratio of particles of the two materials in solution under ultrasonication for 1 h. Next, the dried blended powders were placed in a furnace and annealed at 250 °C for 1 h in an Ar/H<sub>2</sub> flow. The annealed powders were loaded into a graphite die ( $\varnothing$  10 mm  $\times$  10 mm cylinders) and hot-pressed for 5 min at 50 MPa and 250 °C inside an argon-filled glovebox. The hotpressed pellets were then polished and used for TE characterization.

# ■ **RESULTS AND DISCUSSION**

[Figure](#page-1-0) 1a shows a schematic illustration of the aqueous and ambient temperature synthesis process used to produce binary metal chalcogenides (MX;  $M = Ag$ , Cu, Pb, Bi;  $X = S$ , Se). The MX chalcogenide is produced by the reaction of the zerovalent chalcogen  $(X^0)$  powder with  $N_2H_4 \cdot H_2O$  to form  $X^{2-}$  and the immediate reaction of such anions with the metal cations in the metal salt solution. In this way, Ag<sub>2</sub>S, Ag<sub>2</sub>Se, CuS, Cu<sub>2</sub>S, Cu<sub>2</sub>Se, Bi<sub>2</sub>S<sub>3</sub>, Bi<sub>2</sub>Se<sub>3</sub>, PbS, and PbSe particles, which through proper processing can be used in a plethora of different applications,[40](#page-7-0)−[48](#page-7-0) were easily and rapidly obtained. [Figure](#page-1-0) 1b− d displays scanning electron microscopy (SEM) images of Ag<sub>2</sub>Se produced from different AgNO<sub>3</sub>:Se molar ratios; 2:1, 1.9:1, and 1.8:1.  $Ag<sub>2</sub>Se$  particles are characterized by elongated shapes, an average size of a few hundred nanometers, and high crystallinity, as observed by X-ray diffraction (XRD, [Figure](#page-1-0) 1e). XRD patterns show the obtained  $Ag_2Se$  to have an orthorhombic crystallographic phase (PDF 00−024−1041) with lattice parameters *a* = 4.333 Å, *b* = 7.062 Å, and *c* = 7.764 Å. At an AgNO<sub>3</sub>:Se molar ratio of 2:1, a few impurity peaks at 38.2° and 44.3° can be indexed with the cubic Ag phase (PDF 00−004−0783). At a AgNO<sub>3</sub>/Se molar ratio of 1.8:1, a new peak at 29.6° is ascribed to the hexagonal Se phase (PDF 01− 086−2246), indicating that the excess Se was not fully incorporated into the Ag<sub>2</sub>Se lattice. At a AgNO<sub>3</sub>:Se molar ratio of 1.9:1, XRD patterns show pure-phase  $Ag_2Se$ , with no crystalline impurities. Thus, we chose this precursor molar ratio to prepare the material to be further characterized and used to produce  $Ag_2Se/Bi_2S_3$  composites. At this  $AgNO_3:Se$ 

molar ratio of 1.9:1, energy-dispersive X-ray spectroscopy  $(EDX)$  analysis shows the Ag:Se atomic ratio in the final Ag<sub>2</sub>Se particles to be 2.2 ([Figure](https://pubs.acs.org/doi/suppl/10.1021/acsaelm.3c00055/suppl_file/el3c00055_si_001.pdf) S1). However, for the sake of convenience, we denote the silver selenide as  $Ag<sub>2</sub>Se$ . The SEM images, To demonstrate the versatility of the synthesis approach here reported, EDX data and XRD patterns of other MX  $(M = Ag, Cu, Pb, and Bi, X = S and Se)$  are displayed in [Figure](https://pubs.acs.org/doi/suppl/10.1021/acsaelm.3c00055/suppl_file/el3c00055_si_001.pdf) S2, Table S2, and Figure S3, respectively.

Figure 2a shows a general view bright field transmission electron microscopy (TEM) image of produced  $Ag_2Se$ . Figure 2b shows a high-resolution HRTEM micrograph from an Ag2Se particle and its corresponding power spectrum revealing an orthorhombic crystal phase (space group  $P2_12_12_1$ ) with  $a =$ 4.334 Å, *b* = 7.070 Å, *c* = 7.774 Å. The high-angle annular dark field (HAADF) scanning TEM (STEM) micrographs and electron energy loss spectroscopy (EELS) composition maps of Ag2Se particles show a homogeneous distribution of both elements (Figure 2c).

 $Bi<sub>2</sub>S<sub>3</sub>$  particles were also synthesized in an aqueous solution at ambient temperature. Figure 2d,e shows representative SEM and TEM images of the obtained product.  $Bi<sub>2</sub>S<sub>3</sub>$  particles were highly polycrystalline and presented a flowerlike morphology. Crystallites had an average size of ca. 10 nm. EDX analysis showed the atomic ratio of Bi to S to be consistent with stoichiometric  $Bi<sub>2</sub>S<sub>3</sub>$ . HRTEM analysis showed the particle crystal structure to agree with the  $Bi<sub>2</sub>S<sub>3</sub>$  orthorhombic phase (space group = *Pmcn*) with *a* = 3.9810 Å, *b* = 11.1470 Å, and *c* = 11.3050 Å (Figure 2f). EELS compositional maps showed a homogeneous distribution of Bi and S (Figure 2g). Besides,

<span id="page-3-0"></span>

Figure 3. (a) SEM image of the polished Ag<sub>2</sub>Se-1.0 wt % Bi<sub>2</sub>S<sub>3</sub> pellet and corresponding EDX compositional maps of Ag, Se, Bi, and S (Se-rich regions marked with white circles). (b) XRD patterns of consolidated Ag<sub>2</sub>Se-*x* wt % Bi<sub>2</sub>S<sub>3</sub> pellets.

Figure 4. Temperature dependence of (a) Seebeck coefficient and *S*. (b) electrical conductivity,  $\sigma$ . (c) Hall carrier concentration ( $n_H$ ) and mobility  $(\mu_H)$  at room temperature. (d) Power factor PF of Ag<sub>2</sub>Se-*x* wt % Bi<sub>2</sub>S<sub>3</sub>.

XRD data confirmed the orthorhombic phase (PDF 03−065− 3884) of the  $Bi<sub>2</sub>S<sub>3</sub>$  particles ([Figure](#page-2-0) 2h).

 $Ag_2Se/Bi_2S_3$  composites were produced by blending the proper ratio of particles in solution and hot pressing the resulting dried powder at 50 MPa and 250 °C inside an argonfilled glovebox (see the Experimental section for details). An SEM image of the polished surface of the Ag<sub>2</sub>Se-1.0 wt %  $Bi<sub>2</sub>S<sub>3</sub>$ composite and its corresponding EDX elemental maps are <span id="page-4-0"></span>shown in [Figure](#page-3-0) 3a. Besides, the morphology of a fractured Ag<sub>2</sub>Se-1.0 wt %  $Bi<sub>2</sub>S<sub>3</sub>$  sample and its compositional map and EDX compositions of all fractured pellets are shown in [Figure](https://pubs.acs.org/doi/suppl/10.1021/acsaelm.3c00055/suppl_file/el3c00055_si_001.pdf) S4 and [Table](https://pubs.acs.org/doi/suppl/10.1021/acsaelm.3c00055/suppl_file/el3c00055_si_001.pdf) S3. An overall homogeneous distribution of the constituent elements, including S and Bi, is observed, denoting atomic doping of the Ag<sub>2</sub>Se with these two elements. Only some small Se-rich inhomogeneities can be found, as marked with white circles. [Figure](#page-3-0) 3b shows the XRD patterns of the hot-pressed Ag<sub>2</sub>Se- $x$  wt %  $Bi<sub>2</sub>S<sub>3</sub>$  composites, which can be indexed with the orthorhombic Ag2Se phase (PDF 00−024− 1041). As the  $Bi<sub>2</sub>S<sub>3</sub>$  content increases, the XRD peaks shift slightly to lower angles, indicating an expansion of the lattice associated with the partial substitution of  $Ag<sup>+</sup>$  ions (0.67 Å) by  $Bi^{3+}$  ions  $(1.03 \text{ Å})$  with a larger ionic radius.<sup>49</sup> However, when the  $Bi_2S_3$  content exceeds 1.0 wt %, the XRD peaks no longer shift due to the limited solubility of  $Bi^{3+}$  in the matrix. No impurity XRD peaks and particularly  $Bi<sub>2</sub>S<sub>3</sub>$  peaks were detected, indicating notable alloying of  $Bi<sub>2</sub>S<sub>3</sub>$  with  $Ag<sub>2</sub>Se<sup>34</sup>$ The density of the composite slightly decreases with the increase of the  $Bi_2S_3$  fraction due to the lower density of  $Bi_2S_3$ (~6.78 g/cm<sup>3</sup>) compared with Ag<sub>2</sub>Se<sup>[35](#page-7-0)</sup> but all samples reach relative densities above 90% [\(Table](https://pubs.acs.org/doi/suppl/10.1021/acsaelm.3c00055/suppl_file/el3c00055_si_001.pdf) S4).

The temperature dependence of the Seebeck coefficient (*S*) of the different composites is shown in [Figure](#page-3-0) 4a. All samples show n-type semiconducting behavior with negative S values. The absolute values of S monotonously decrease with temperature over the entire measured range. The *S* of the pure Ag2Se sample reaches up to −158.4 *μ*V/K at 300 K and decreases to −146.7 *μ*V/K at 390 K. With the introduction of  $Bi<sub>2</sub>S<sub>3</sub>$ , the absolute *S* values increased significantly reaching up to  $-178.5 \mu$ V/K at 300 K for the Ag<sub>2</sub>Se-1.0 wt % Bi<sub>2</sub>S<sub>3</sub> pellet.

As displayed in [Figure](#page-3-0) 4b, the temperature dependence of the electrical conductivity  $(\sigma)$  of the different composites shows a typical nondegenerate semiconductor characteristic with  $\sigma$  monotonously increasing with temperature. Relatively similar  $\sigma$  values were obtained for the different doping composites.

The charge carrier concentration ( $n_{\rm H}$ ) and mobility ( $\mu_{\rm H}$ ) as a function of the  $Bi<sub>2</sub>S<sub>3</sub>$  amount were measured by Hall and are displayed in [Figure](#page-3-0) 4c. As the concentration of  $Bi<sub>2</sub>S<sub>3</sub>$  increases, the  $n_H$  for Ag<sub>2</sub>Se-*x* wt %  $Bi_2S_3$  exhibits a moderate decrease  $(6.4 \times 10^{18} \text{ cm}^{-3}$  for pure Ag<sub>2</sub>Se and  $4.9 \times 10^{18} \text{ cm}^{-3}$  for Ag<sub>2</sub>Se-1.5 wt % Bi<sub>2</sub>S<sub>3</sub>). In contrast, the  $\mu_H$  for Ag<sub>2</sub>Se-*x* wt %  $Bi<sub>2</sub>S<sub>3</sub>$  samples first rises and then decreases gradually with rising Bi<sub>2</sub>S<sub>3</sub> concentration. In detail, the  $\mu$ <sub>H</sub> is 958.9 cm<sup>2</sup> V<sup>-1</sup>  $s^{-1}$  for the pure Ag<sub>2</sub>Se sample, and the largest value of 1310.4  $\text{cm}^2 \text{ V}^{-1} \text{ s}^{-1}$  is found as  $\text{Bi}_2 \text{S}_3$  amount increases to 1.0 wt %. A further increase of  $Bi<sub>2</sub>S<sub>3</sub>$  doping concentration to 1.5 wt % reduces the  $\mu_H$  of Ag<sub>2</sub>Se-*x* wt % Bi<sub>2</sub>S<sub>3</sub> samples.

The increase in the absolute value of the Seebeck coefficient with the introduction of  $Bi<sub>2</sub>S<sub>3</sub>$  is in part associated with the decrease in the charge carrier concentration. Previous studies also demonstrate an increase in the absolute value of the Seebeck coefficient and also the charge carrier mobility with the partial replacement of Se with  $S<sup>13,50</sup>$  $S<sup>13,50</sup>$  $S<sup>13,50</sup>$  $S<sup>13,50</sup>$  Besides, the Bi doping within the Ag<sub>2</sub>Se lattice expands the lattice, as observed by XRD, which according to previous publications could increase the density of states near the Fermi level,  $51-53$  $51-53$  $51-53$  thereby further enhancing the Seebeck coefficient of the Ag<sub>2</sub>Se-based materials. At too high,  $Bi<sub>2</sub>S<sub>3</sub>$  precipitates are found as a secondary phase inside the Ag<sub>2</sub>Se matrix, which reduces the charge carrier mobility and the absolute value of the Seebeck coefficient. This reduction may be related to a higher bipolar

contribution associated with the preferential scattering of electrons over holes at the  $Ag_2Se/Bi_2S_3$  interphase owing to the upward band bending generated at the  $Ag_2Se$  side. It is therefore crucial to maintain the  $Bi<sub>2</sub>S<sub>3</sub>$  content below 1% to achieve an optimal thermoelectric performance in Ag<sub>2</sub>Se−Bi<sub>2</sub>S<sub>3</sub> composites. Notice that a similar evolution of the Seebeck coefficient with dopant concentration, first increasing and later decreasing at higher dopant concentrations, has been reported in other systems, and diverse mechanisms have been reported.[54](#page-7-0)−[57](#page-8-0) Besides, previous studies have also shown increased Seebeck coefficients without affecting the electrical conductivity.[58](#page-8-0)−[60](#page-8-0) The preserved electrical conductivity of Ag<sub>2</sub>Se after being mixed with  $Bi<sub>2</sub>S<sub>3</sub>$  is attributed to the notable increase in charge carrier mobility, which compensates for the moderate decrease in charge carrier concentration.

[Figure](#page-3-0) 4d shows the power factor (PF,  $S^2\sigma$ ) of Ag<sub>2</sub>Se-*x* wt %  $Bi<sub>2</sub>S<sub>3</sub>$  samples as a function of temperature. For the pure  $Ag<sub>2</sub>Se$ sample, the PF slightly increases, from 2.06 to 2.24 mW m<sup>-1</sup> K<sup>-2</sup> over 300–390 K. The PF of the Ag<sub>2</sub>Se −1.0 wt % Bi<sub>2</sub>S<sub>3</sub> composite is significantly larger, reaching up to 2.66 mW  $m^{-1}$ K<sup>-2</sup> at 360 K. Notice also that the Ag<sub>2</sub>Se-1.0 wt % Bi<sub>2</sub>S<sub>3</sub> pellet exhibits good stability even after multiple tests ([Figure](https://pubs.acs.org/doi/suppl/10.1021/acsaelm.3c00055/suppl_file/el3c00055_si_001.pdf) S5).

The experimental thermal diffusivities, *α*, are presented in [Table](https://pubs.acs.org/doi/suppl/10.1021/acsaelm.3c00055/suppl_file/el3c00055_si_001.pdf) S4. The measured heat capacities,  $C_p$ , and the limit  $C_p$ calculated by the Dulong−Petit law are shown in [Figure](https://pubs.acs.org/doi/suppl/10.1021/acsaelm.3c00055/suppl_file/el3c00055_si_001.pdf) S6. Notice that while the measured *C*<sup>p</sup> is very close to the calculated limit for the  $Ag_2Se-x$  wt %  $Bi_2S_3$  composite and slightly below this limit for the pure Ag<sub>2</sub>Se sample, the limit is approximately within the error range of the measured values.<sup>[61,62](#page-8-0)</sup> The total thermal conductivity ( $\kappa_{\text{tot}}$ ) is determined by the equation

$$
\kappa_{\rm tot} = \alpha \rho C_{\rm p} \tag{3}
$$

where  $\rho$  is density. Figure 5a displays the obtained thermal conductivity of Ag<sub>2</sub>Se and Ag<sub>2</sub>Se-*x* wt %  $Bi<sub>2</sub>S<sub>3</sub>$  samples over the

Figure 5. Thermal conductivity of (a) total thermal conductivity,  $\kappa_{\text{tot}}$ . (b) Lattice thermal conductivity  $\kappa_L$ .

whole temperature range. The pure  $Ag_2Se$  pellet is characterized by a moderate  $\kappa_{\text{tot}}$  of 0.99 W m<sup>-1</sup> K<sup>-1</sup> at 300 K and 1.15 W  $m^{-1}$  K<sup>-1</sup> at 390 K. These values are consistent with previous reports on  $Ag_2Se^{25}$  $Ag_2Se^{25}$  $Ag_2Se^{25}$  With the introduction of Bi<sub>2</sub>S<sub>3</sub>, *κ*<sub>tot</sub> significantly decreases. The Ag<sub>2</sub>Se-1.5 wt % Bi<sub>2</sub>S<sub>3</sub> sample displayed the lowest  $\kappa_{\text{tot}}$ , 0.76 W m<sup>-1</sup> K<sup>-1</sup> at 300 K and 0.90 W m<sup>−</sup><sup>1</sup> K<sup>−</sup><sup>1</sup> at 390 K. Figure 5b displays the lattice thermal conductivity  $(\kappa_L)$  obtained by subtracting the electronic contribution to the thermal conductivity calculated using a single parabolic band (SPB) model according to Wiedemann–Franz ( $\kappa_e$  =  $L\sigma T$ , where *L* is the Lorentz number) from the total thermal conductivity ( $\kappa_L = \kappa_{tot} - \kappa_e$ ). The Lorenz number *L* is calculated by

<span id="page-5-0"></span>
$$
L = 1.5 + \exp\left[-\frac{|S|}{116}\right] \tag{4}
$$

The plot is displayed in [Figure](https://pubs.acs.org/doi/suppl/10.1021/acsaelm.3c00055/suppl_file/el3c00055_si_001.pdf) S7a. [Figure](https://pubs.acs.org/doi/suppl/10.1021/acsaelm.3c00055/suppl_file/el3c00055_si_001.pdf) S7b shows the temperature dependence of  $\kappa_e$ . While similar  $\kappa_e$  values were obtained for the different materials, composites displayed lower  $\kappa_L$ , down to 0.34–0.17 W m<sup>-1</sup> K<sup>-1</sup> for Ag<sub>2</sub>Se-1.5 wt %  $Bi<sub>2</sub>S<sub>3</sub>$ . The lower  $\kappa_{\text{tot}}$  measured for the composites is associated with a more effective scattering of phonons at point defects created by  $Bi^{3+}$  and extensive interphases between Ag<sub>2</sub>Se and  $Bi<sub>2</sub>S<sub>3</sub>$  in the case of the highest doped samples. Numerous previous works have reported a decrease of thermal conductivity with a minor effect on electrical conductivity and have associated this phenomenon with different explanations, including a strong scattering on phonons created by precipitates without strongly affecting electrical conductiv- $ity<sub>0</sub><sup>63</sup>$  $ity<sub>0</sub><sup>63</sup>$  $ity<sub>0</sub><sup>63</sup>$  hierarchical architecture with multiscale defects differently affecting phonons and electrons, $60$  phonon scattering by introduced electrically dopant atoms, $64$  and preferential phonon scattering by introduced nanoparticles.<sup>[65](#page-8-0)</sup>

The temperature dependence of the TE figure or merit, *zT*, is displayed in Figure 6a. For the pristine Ag<sub>2</sub>Se pellet, the  $zT$ 

Figure 6. Temperature dependence of (a)  $zT$  values of Ag<sub>2</sub>Se- $x$  wt %  $Bi_2S_3$ , (b) a comparison with reported silver selenide-based thermo-electric materials,<sup>5,[10,19](#page-6-0)[,25,](#page-7-0)[66](#page-8-0),[69](#page-8-0),[70](#page-8-0)</sup> and (c) a comparison of  $zT_{\text{ave}}$  with reported data of silver selenide-based thermoelectric materi $a$ ls.<sup>5,[11](#page-6-0),[13,15,18,](#page-6-0)[68](#page-8-0)</sup>

value increases from 0.62 at 300 K to 0.76 at 380 K. The *zT* values of the Ag<sub>2</sub>Se- $x$  wt %  $Bi<sub>2</sub>S<sub>3</sub>$  composites increase with the introduction of  $0.5-1.0$  wt %  $Bi<sub>2</sub>S<sub>3</sub>$ . A maximum  $zT$  value of 0.96 was obtained for the Ag<sub>2</sub>Se-1.0 wt %  $Bi<sub>2</sub>S<sub>3</sub>$  sample at 370 K, which is ascribed to the highest PF value and slightly decreased  $\kappa_{\text{tot}}$ . These  $zT$  values are above those previously reported n-type Ag<sub>2</sub>Se -based TE materials prepared by wet chemistry $^{18,19,22,23,25,27,66}$  $^{18,19,22,23,25,27,66}$  $^{18,19,22,23,25,27,66}$  $^{18,19,22,23,25,27,66}$  $^{18,19,22,23,25,27,66}$  $^{18,19,22,23,25,27,66}$  and other methods  $^{15,32,67,68}$  $^{15,32,67,68}$  $^{15,32,67,68}$  $^{15,32,67,68}$  $^{15,32,67,68}$  $^{15,32,67,68}$  [\(Figure](#page-4-0) [5](#page-4-0)b and [Table](https://pubs.acs.org/doi/suppl/10.1021/acsaelm.3c00055/suppl_file/el3c00055_si_001.pdf) S5). We further determined the thermoelectric properties of a pure Ag2Se sample up to 480 K ([Figure](https://pubs.acs.org/doi/suppl/10.1021/acsaelm.3c00055/suppl_file/el3c00055_si_001.pdf) S8). We noticed that above 400 K, coinciding with the Ag<sub>2</sub>Se phase transition, a large decrease in the absolute value of the Seebeck coefficient and electrical conductivity was obtained, which

resulted in an abrupt drop of *zT*. Thus, the material application is limited to a temperature range extending up to about 390 K.

*zT* values remain constant throughout the whole temperature range tested, providing a high average *zT* (*zT*ave) calculated as

$$
zT_{\text{ave}} = \frac{1}{T_{\text{h}} - T_{\text{c}}} \int_{T_{\text{c}}}^{T_{\text{h}}} zT dT \tag{5}
$$

where  $T<sub>h</sub>$  is the hot-side temperature,  $T<sub>c</sub>$  is the cold-side temperature, and  $zT_{ave}$  is thus the area under the  $zT$  curve divided by the value of  $T_h - T_c$ . As shown in Figure 6c, a  $zT_{ave}$ = 0.93 is obtained in the temperature range of 300 to 390 K for the Ag<sub>2</sub>Se-1.0 wt %  $Bi<sub>2</sub>S<sub>3</sub>$  sample, significantly above previously reported values.

## ■ **CONCLUSIONS**

In conclusion, a facile, rapid, high-yield, and componentcontrollable room-temperature aqueous synthesis method was adopted to prepare a plethora of metal chalcogenide MX nanoparticles ( $M = Ag$ , Cu, Pb, Bi;  $X = S$ , Se). Using this procedure, a series of Ag<sub>2</sub>Se- $x$  wt %  $Bi<sub>2</sub>S<sub>3</sub>$  composites was obtained by blending the materials in solution and hot press sintering the obtained dried powder. A maximum *zT* value of 0.76 for pure Ag2Se was obtained at 380 K. Further investigation illustrates that moderate  $Bi<sub>2</sub>S<sub>3</sub>$  doping can effectively increase the absolute S value and reduce  $\kappa$ <sub>L</sub> without significant harm to *σ*, which contributes to a remarkable PF of 2.66 mW m<sup>−</sup><sup>1</sup> K<sup>−</sup><sup>2</sup> and a maximum *zT* of 0.96 at 370 K. Besides, a remarkable  $zT_{\rm ave}$  of 0.93 was obtained for Ag<sub>2</sub>Se-1.0 wt %  $Bi<sub>2</sub>S<sub>3</sub>$  nanocomposites, above the values obtained in most previous silver selenide-based thermoelectric materials fabricated via wet chemical approaches.
